

Acute ST-elevation Myocardial Infarction and heavily calcified lesion

Francesco Colombo, MD

San Giovanni Bosco Hospital, Turin, Italy

65 years-old woman

Cardiovascular risk factors: Hypertension, Dyslipidemia, Smoke, Familiar history of coronary artery disease

18 Sep 2020, **1 am** access to emergency department for 5-hour retrosternal chest pain

BP 140/65 mmHg

HR 75 bpm

SpO2 96%

Killip 1

Fast echo: 45% LVEF,

inferoposterior akinesia, normal RV, no pericardial effusion

Urgent coronary angiography

Pre-treatment with oral loading doses of Aspirin 300 mg + Prasugrel 60 mg

**Easy occlusion crossing
(RunThrough™ wire)**

Check after wire crossing

**Thrombus aspiration catheter
doesn't cross the lesion ...**

**... neither 2.0, 1.5, 1.20 mm semi-
compliant balloons !!!**

**1.2 mm balloon crosses the lesion
with 5.5 Fr Guideliner™ support...**

2.5 mm NC balloon

!!!

Rotational atherectomy

**Finecross™ 130 cm microcatheter
used to exchange workhorse
wire to a RotaWire™ Floppy**

**Now 2.5 mm NC balloon crosses
the lesion without need for
mother-in-child support ...**

... but still doesn't expand !!!

Coronary lithotripsy

Primary PCI from 6 French right radial access and 6 French guiding catheter: no possibility of significant burr size upgrade

↓
SHOCKWAVE Coronary IVL System™ (3.0 x 12 mm balloon)

RCA stenting & post-dilations

2.75 x 34 mm DES

A fluoroscopic image showing a drug-eluting stent (DES) deployed in the right coronary artery (RCA). The stent is a thin, dark, curved line against the lighter background of the coronary artery and surrounding tissue.

← **3.5 mm NC balloon**

A fluoroscopic image showing a non-compliant (NC) balloon catheter positioned in the RCA. A white arrow points to the balloon, which is a thin, curved line.

← **3.25 mm NC balloon**

A fluoroscopic image showing a second non-compliant (NC) balloon catheter positioned in the RCA, just below the first balloon. A yellow arrow points to this second balloon.

3.0 x 34 mm DES

A fluoroscopic image showing a second drug-eluting stent (DES) deployed in the RCA, overlapping with the first stent. It appears as a dark, curved line.

Final angiographic result

At the end of the procedure:

- chest pain regression
- BP 105/65 mmHg

Troponin peak 2.58 ng/ml

LAD/diagonal PCI (minicrush) on day 4

Discharged on day 6

Echo at discharge: LVEF 54%, normal RV

At 6 months follow-up asymptomatic, no adverse events

- The concomitant existence of acute ST-elevation myocardial infarction (STEMI) and truly undilatable lesions is not a common circumstance, but may occur.
- Despite generally avoided in high thrombotic states, rotational atherectomy may serve as an alternative option when standard interventions fail.
- Nevertheless, in this case the lesion continued to be undilatable after successful rotablation and the solution was provided by coronary intravascular lithotripsy.
- However rotational atherectomy facilitated devices advancement, lithotripsy balloon included.
- Ultimately the combination of both techniques allowed successful treatment.
- To the best of our knowledge this is the first report of combination of both debulking techniques in primary angioplasty.
- Complex coronary lesions in STEMI patients may require familiarity with all techniques / devices dedicated to calcified lesions treatment.
